Conditioning sensitivity across four perturbation axes
(a) Magnitude: U-shaped, steeper when too dry
(statistic uses the folded distance |log2 factor|)
BPD relative to own baseline
log2(magnitude factor) [0 = truth]
(b) Shift: monotonic response
BPD relative to own baseline
shift (pixels)
(c) Blur: dip, then rise
(mild blur decreases BPD, aggressive blur increases it)
BPD relative to own baseline
blur sigma (pixels)
(d) Swap: all 20 fields above the line
swap BPD (different day's conditioning)
baseline BPD (true conditioning)
